The cardiovascular system is one of the most complex and elegant systems in our body. The circadian variation in its activity has been known for a long time. The cardiovascular system is an important regulator of the metabolic and hormonal conditions necessary for normal and successful growth and development. The normal pattern of cardiac function and hemodynamics can be assessed from continuous electrocardiographic recordings, continuous blood pressure and central venous pressure recordings. In order to obtain information on the circadian variation of cardiovascular parameters, a systematic evaluation is necessary. Significant variations have been reported in the 24-hour activity of the cardiovascular system. Such variations have been observed in almost every component of the cardiovascular system (heart rate, arterial blood pressure, cardiac function, ventricular repolarization, baroreflex sensitivity, sympathetic activation and release, reflexes and hormones). This variation can be explained by the circadian rhythm of the sympathetic nervous system (SNS) and the brain-autonomic nervous system (ANS). Most of the cardiovascular parameters are higher during the day-time and lower during the night-time. An increased SNS activity during the day-time is responsible for an increase in the cardiac output. In contrast, a decrease in SNS activity during the night-time results in a decrease of the cardiac output. During the night-time an increased activity of the parasympathetic nervous system (PSNS) occurs which may result in a fall in the heart rate and arterial blood pressure.You have javascript disabled.
